Guarded surgical scalpel.

A surgical scalpel (100) has a hollow handle (101) provided with a cleat (104), and the cleat (104) has a rib (105) for mounting a blade (106). A guard (107) is telescopically received within the hollow handle (101) for sliding movement therein. The guard (107) has an advanced position in which the blade (106) is covered and an alternate retracted position in which the blade is exposed for use during a surgical procedure. The guard (107) is an inverted U-shaped channel including a pair of side walls (109, 110) having respective closed longitudinal slots (122, 123) formed therein. A pin (121) is carried by the handle (101) transversely thereof and is received in the closed longitudinal slots (122, 123), thereby providing a bearing guide means and a stop means (120) between the guard (107) and the handle (101). A resiliently-based detent means (113) is provided between the guard (107) and the handle (101), and the detent means (113) is independent of the stop means (120).

CROSS REFERENCE TO RELATED APPLICATION

The present invention constitutes an improvement to European Patent Application No. 93870010.1 filed on January 21, 1993.

FIELD OF THE INVENTION

The present invention relates to a surgical scalpel and, in particular, to a surgical scalpel having a retractable blade guard to protect against inadvertent nicks or cuts during a surgical procedure in an operating room.

BACKGROUND OF THE INVENTION

Scalpels are regularly used by surgeons and other health care professionals for making incisions during an operating procedure. Typically, the operating room assistant (which may be a nurse, technician or another doctor) "slaps" the scalpel into the surgeon's hand in a predetermined orientation, so that the surgeon can "feel" the scalpel and automatically grip its handle without taking his or her eyes away from the patient or the instrumentation. If the predetermined orientation is not closely followed, the nurse's or surgeon's hand may be cut or nicked. The same hazard may be encountered when the surgeon transfers the scalpel back to the assistant.

These nicks or cuts, besides being uncomfortable and distracting, may result in blood or body fluid exposure from the patient to the surgeon or other health care professional (and vice versa) and hence may lead to the spreading of infectious diseases. Concern over this situation has become especially acute since the appearance of the human immune deficiency virus (or "HIV"). Indeed, such cuts have already been blamed, by some health care providers, for cases of HIV infection in their profession. Consequently, some individual surgeons or health care providers have stopped performing surgical operations, rather than risk the chances of inadvertently contracting the deadly HIV from an infected patient. There are similar concerns with the Hepatitis B virus (or "HBV").

The risks associated with scalpel cuts during an operating room procedure are greater than those associated with needle sticks; but even there, the problem is becoming alarming. In a study made by the Needle Stick Surveillance Group of the Center For Disease Control ("CDC") out of 3,978 known punctures from patients known to be HIV positive, 13 health care workers got infected or roughly 1 out of 300. Thus, from a single needle stick while treating an AIDS patient in an operating room or other environment, the chances are roughly 1 out of 300 that the surgeon, nurse or other individual health care provider will sero-convert and become HIV positive. If a sur-

geon, nurse or assistant is cut by a scalpel while conducting a surgical procedure in an operating room (rather than a needle stick) the risk is much greater simply because, first, there is more blood involved and, secondly, the surface area of the wound is larger.

In order to solve this problem, the prior art has disclosed guarded scalpels. Examples are U.S.A. patents nos. 3,906,626 and 5,071,426 and German Offenlegungsschrift DE 37 22 899 A1. However, and for various reasons, these guarded scalpels are not completely satisfactory; hence are not in current widespread use in hospitals and clinics.

The prior art has also disclosed a microsurgical knife with a locking blade guard, as for example, U.S.A. patent 4,735,202 used for ophthalmological purposes. The structure and intended purpose, however, are not suitable for general surgical use.

Another example of the prior art is U.S.A. patent 4,499,898, which discloses a surgical knife with a controllably extendable blade and a gauge therefor. Again, this disclosure is intended for very delicate surgery and is not suitable for a general purpose guarded scalpel.

While general-purpose utility knives have been provided with slidable guards, these are hardware items and are not readily suitable for use in surgical procedures.

While protective gloves aid in reducing the chances of being cut during a surgical procedure, these gloves are by no means foolproof; and such cuts are still quite common. Even when two sets of gloves are utilized, full protection is not afforded to the health care provider, for many times the blade cuts right through both sets of gloves. Also, utilizing two sets of gloves reduces finger dexterity and is distracting, interfering with the intended surgical procedure.

This situation has become so pronounced that some leading surgeons, as well as nurses and other individual health care providers, have abandoned their respective practices altogether.

In the operating room, time is of the essence and seconds count; the mental concentration and physical effort are intense; and distractions must be avoided at all times.

SUMMARY OF THE INVENTION

Accordingly, the present invention provides a guarded scalpel for general surgery, wherein the blade guard may be retracted and advanced, alternately, and in a one-hand operation without taking one's eye away from the patient or the instrumentation. When transferring the guarded scalpel from the nurse to the surgeon and vice versa, the recipient will know intuitively from the "feel" of the guarded scalpel itself that, first, the guard has been advanced to cover the blade and, second, the relative orientation of the guarded scalpel itself, that it, whether the cutting

edge on the covered blade is "up or "down".

The guard closely follows the slim-line contours of the scalpel handle, so that the guard is not cumbersome or obtrusive; rather, the guarded scalpel has a good "feel" and balance; is comfortable to use, and does not distract the surgeon nor interface with his or her concentration. Moreover, a two-position resiliently-biased detent means provides an auditory "click", signalling that the guard has been moved into an alternate position, and precluding an inadvertent and undesirable movement of the guard during transfer or use of the guarded scalpel. This detent means may be manually released --- in a one-hand movement without taking one's eyes off the patient or the instrumentation --- for movement of the guard into an alternate position.

The present invention constitutes an improved guarded surgical scalpel having a handle with a blade mounted thereon. In accordance with the improvement, the handle is substantially hollow and has a sliding guard telescopically mounted therein. A two-position detent means is provided between the guard and the handle, thereby defining an advanced position of the guard in which the blade is substantially covered and an alternate retracted position of the guard in which the blade is exposed. A bearing guide means is provided for the guard. This bearing guide means includes a pin carried transversely of the handle, and the guard includes at least one side wall having a longitudinal slot formed therein and receiving the pin.

Preferably, the guard is formed as an inverted U-shaped channel having a pair of side walls, each of which has a longitudinal slot formed therein for receiving the pin. These longitudinal slots are closed at each end thereof, such that the bearing guide means provides a stop means for limiting the alternate advanced and retracted positions of the guard with respect to the handle, the stop means being independent of the detent means.

The detent means includes a detent member carried by one of the handle and guard, and the other of the handle and guard has a longitudinal slot receiving the detent member.

This longitudinal slot has a pair of spaced-apart detent pockets for alternately receiving the detent member.

A detent button is disposed above the handle, the detent button releasing the detent member from a respective detent pocket.

The handle includes a lower member having a longitudinally-extending section constituting a cleat, and the cleat is provided with a rib for mounting the blade thereon.

The present invention thus substantially reduces the risk of the surgeon, nurse or assistant inadvertently acquiring (or transmitting) an infectious disease, such as HIV or HBV, in the operating room or

similar medical environment.

These and other objects of the present invention will become readily apparent from a reading of the following description of the present invention, taken in conjunction with the enclosed drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

Fig. 1 is a perspective view of an operating room or theater where the improved surgical scalpel, equipped with the protective blade guard of the present invention, will be utilized.

Fig. 2A is an enlarged view of a conventional (unguarded) scalpel, illustrating how an assistant may be cut or nicked when transferring the scalpel during an operating procedure.

Fig. 2B is an enlarged view of a conventional scalpel, corresponding substantially to Fig. 2A, but showing how the surgeon may be cut or nicked when transferring the scalpel.

Fig. 3A illustrates how the improved scalpel of the present invention protects the assistant's hand when passing the scalpel to the surgeon during an operation.

Fig. 3B illustrates how the guard on the improved scalpel is easily and conveniently retracted by the surgeon --- with one hand --- to expose the blade.

Fig. 3C illustrates how the guard is easily and conveniently advanced by the surgeon --- again, with only one hand --- to cover the blade.

Fig. 3D illustrates how the guarded scalpel of the present invention protects the assistant's hand when the surgeon passes the scalpel back to the assistant.

Fig. 4 is a side elevation of the scalpel of the present invention with the protective guard in a first advanced position to cover the blade.

Fig. 5 is a side elevation of the scalpel of the present invention with the protective guard in a second retracted position, thereby exposing the blade.

Fig. 6 is a cross-sectional view, taken along lines 6-6 of Fig. 4, drawn to an enlarged scale, and showing the manually-releasable detent means for the guard.

Fig. 6A is a cross-sectional view thereof, taken across the lines 6A-6A of Fig. 6, and showing the annular collar on the spring-loaded detent pin received in a respective detent pocket formed on the guard.

Fig. 7 is a cross-sectional view taken along lines 7-7 of Fig. 6, showing the means for retaining the detent means on the body or handle of the scalpel.

Fig. 8 is a cross-sectional view taken along lines 8-8 of Fig. 4, drawn to an enlarged scale, and showing the stop means for the guard.

Fig. 9 is an exploded perspective view of the improved scalpel with its blade guard.

Fig. 10 corresponds substantially to Fig. 6, but shows a cap or button on the releasable detent means for the blade, thereby providing a preferred tactile means and facilitating manual release of the

detent means.

Fig. 11 is an alternate embodiment of the detent means.

Fig. 12 is a cross-sectional view thereof, taken along lines 12-12 of Fig. 11.

Figs. 13A-13D show, respectively, the manner in which the guard may be manually retracted to expose the blade on the scalpel, and then advanced to cover the blade to protect against inadvertent cuts and nicks normally occasioned in transferring the scalpel from the nurse to the surgeon, and vice versa, during a surgical procedure; wherein the thumb engages the releasable detent pin (or button) and the forefinger is received in the cut-out formed in the bottom wall of the U-shaped sliding guard to alternately retract and advance the guard.

Figs. 14A-14D correspond substantially to that of Figs. 13A-13D, but show an alternate manner for selectively and alternately retracting and advancing the sliding guard, wherein the forefinger releases the detent pin, and wherein the thumb engages the cut-out in the bottom wall of the guard; the surgeon may then use the scalpel to cut in a generally upwardly direction or may pivot his or her wrist to cut in a generally downwardly direction, as desired.

Fig. 15 is a side elevational view of an improved blade mounted on the scalpel.

Fig. 16 is a partial exploded view, corresponding substantially to Fig. 15, but showing the manner in which the improved blade is mounted on the scalpel.

Fig. 17 is a side elevational view of the improved blade of the present invention mounted on a conventional (non-guarded) surgical scalpel.

Fig. 18 corresponds substantially to Fig. 6, but shows a tapered portion of the detent member received within a respective detent pocket, thereby providing an improved detent action between the guard and the handle of the guarded scalpel.

Fig. 19 is an exploded elevational view, corresponding substantially to a portion of Fig. 18 drawn to an enlarged scale, and showing the tapered portion of the detent member initially engaging a respective detent pocket.

Fig. 20 shows the detent member fully seated in its respective detent pocket.

Fig. 21 is a perspective view of another (and preferred) embodiment of the guarded scalpel of the present invention, showing the guard in the form of an inverted U-shaped channel telescopically mounted within the handle of the scalpel for sliding movement therein, the guard being shown in its advanced position substantially covering the blade.

Fig. 22 is a further perspective view, corresponding substantially to that of Fig. 21, but showing the guard retracted within the handle to expose the blade.

Fig. 23 is a longitudinal cross-sectional view of the preferred guarded scalpel, taken along the lines 23-23 of Fig. 21.

Fig. 24 is an end view of the guarded scalpel of Fig. 23.

Fig. 25 is a cross-sectional view of the guarded scalpel, taken along the lines 25-25 of Fig. 23, and drawn to an enlarged scale.

GENERAL DESCRIPTION OF THE PREFERRED EMBODIMENTS

With reference to Figs. 1, 2A and 2B, the situation in a typical operating room ("O.R.") is tense and, quite often, the patient's life is at stake. The scalpel blade is very sharp; and in passing a conventional unguarded scalpel S from the nurse (or other assistant) to the surgeon, and vice versa, it is not at all unusual for the surgeon or the nurse to be nicked or cut by the scalpel blade, as shown in Figs. 2A and 2B. This is a dangerous situation, especially aggravated by current viruses and, besides, is painful and distracting.

Accordingly, and with reference to Figs. 3A-D, the guarded scalpel 10 of the present invention has a unique guard 11 for the blade 12. The blade 12 is conventional and is removably mounted on the scalpel 10 (as hereinafter described). The scalpel 10 may be passed from the nurse to the surgeon in an guarded position (Fig. 3A) to prevent the nurse from being cut. Thereafter, the surgeon may retract the guard 11 in a one-handed movement (Fig. 3B) to expose the blade 12. After making one or more incisions, the surgeon may advance the guard (Fig. 3C) --- again, in a one-handed movement and without taking his or her eyes away from the patient or the instrumentation in the O.R. --- and pass the scalpel 10 back to the nurse (Fig. 3D). The risk of getting cut has been substantially reduced, if not eliminated altogether.

It will be appreciated, of course, that various guarded scalpels 10 may be passed back and forth in the O.R. during a lengthy procedure on a patient.

With reference to Figs. 4-9, the guard 11 is substantially U-shaped and closely conforms to the outer contours of the scalpel 10. The guard 11 includes parallel side walls 13 and 14, a bottom wall 15, and a top portion 16. The top portion 16 includes a pair of intumed flanges 17 and 18, respectively, defining a slot 19 therebetween. These intumed flanges 17 and 18 are received in longitudinal guide tracks 20 and 21 formed in the sides 22 and 23, respectively, in the body portion or handle 24 of the scalpel 10, thereby slidably mounting the guard 11 on the handle 24.

A stop means is provided to limit the sliding movement of the guard 11. Preferably, the side wall 14 of the guard 11 has a closed longitudinal slot 25 formed therein; and a pin 26 passes through the closed longitudinal slot 25 and is secured within a transverse bore 27 in the handle 24, thereby restricting the longitudinal sliding movement of the guard 11 and defining its alternate advanced and retracted positions, respectively. Preferably, the pin 26 is a split sleeve as

shown more clearly in Fig. 8.

A two-position resiliently-biased manually-manipulatable detent means 28 is provided between the guard 11 and the handle 24 of the scalpel 10. This detent means 28, which is manually releasable, positively locks the guard 11 in its selected position and precludes inadvertent or accidental movement thereof.

The preferred detent means 28 includes a resilient-biased detent member 29. The detent member 29 is carried by the handle 24 and is disposed substantially within the (vertical) longitudinal midplane or center plane 30 thereof, as shown more clearly in Fig. 6, and about an axis which is substantially perpendicular to the longitudinal axis of the guard 11. Thus, the detent member 29 is backed up substantially by the material portion of the handle 24 --- the detent member 29 is not disposed laterally thereof --- and minimizes the extended outer contours of the guarded scalpel 10.

The detent member 29 includes a stem 31, an intermediate collar 32, and an upwardly-projecting portion or button 33. The handle 24 has a bore 34 communicating with a counterbore 35 and a cross-cut 36, respectively. Stem 31 of the detent member 29 is slidably guided in the bore 34, so that the detent member 29 has a smooth inward movement without being cocked. A coil spring 37 is within the counterbore 35 and bears against the collar 32, thereby constantly urging the detent member 29 outwardly (upwardly) of the handle 24; and the collar 32 is slidably received within the cross-cut 36. The button 33 passes through an opening 38 in a retaining plate 39, and the retaining plate 39 is secured to the handle 24 by a screw 40 received in a tapped recess 41. As shown more clearly in Figs. 6A and 9, a pair of longitudinally-spaced detent pockets 42 and 43 are formed in the inturred flanges 17 and 18 on the guard 11 to receive, alternately, the collar 32 on the detent member 29.

When the detent member 29 is manually depressed inwardly against the force of the coil spring 37, the collar 32 clears its respective detent pocket 42 or 43 and allows the guard 11 to be slidably moved along the handle 24 and into its alternate position. When the collar 32 is received in detent pocket 42, the guard is advanced (forwardly) on the handle 24 to cover the blade 12 and prevent accidental contact with the blade 12 during transfer of the scalpel 10; and when the collar 32 is received in detent pocket 43, the guard 11 is retracted (rearwardly) on the handle 24 to expose the blade 12 during an operating procedure.

To facilitate depression of the detent member 29, a cap 44 may be provided (as shown more clearly in Fig. 10).

With reference to Figs. 11 and 12, an alternate embodiment of the detent member 29 comprises a detent ball 45 resiliently biased by a spring 46. The spring 46 is in a blind bore 47, and the detent ball 45 is slidably guided in a counterbore 48.

With reference again to Figs. 4, 5 and 9, the bottom wall 15 of the guard 11 has a cut-out 49 extending upwardly into the respective side walls 13 and 14 of the guard 11. This cut-out 49 is intended to receive either the thumb or forefinger of the recipient and thereby facilitate manual movement of the guard 11.

With reference to Figs. 13A-D and 14A-D, the features and advantages of the present invention will be readily appreciated.

When the guarded scalpel 10 is placed in the hand of the surgeon (or passed back to the nurse), the surgeon (or nurse) will know intuitively from the "feel" of the scalpel 10, first, that the guard 11 is "on" (that is, the blade 12 is covered by the guard 11) but will also know, secondly, the orientation of the scalpel 10 (that is, whether the cutting edge of the blade 12 is pointed "up" or "down"). Most surgeons prefer to make incisions with the blade 12 "down", some with the blade 12 "up", and some surgeons use both orientations depending upon the nature of the required incision.

In Figs. 13A-D, the blade 12 is "down". In Fig. 13A, the surgeon grasps the scalpel 10, such that the surgeon's thumb is on the upwardly-projecting button 33 on the detent member 29, and the surgeon's forefinger is in the cut-out 49. In Fig. 13B, the button 33 is depressed, and the guard 11 is moved rearwardly to expose the blade 12. After the incision (or incisions) have been made, the button 33 is again depressed by the surgeon's thumb while the surgeon's forefinger is in the cut-out 49 (Fig. 13C) and, thereafter, the guard 11 is moved forwardly (Fig. 13D) to cover the blade 11.

In Figs. 14A-D, a similar sequence is followed. There, however, the cutting edge of the blade is "up", and the surgeon's thumb is in the cut-out 49 while his or her forefinger is on the button 33.

In summary, the features and advantages of the present invention are as follows: When the scalpel 10 is passed from the nurse to the surgeon (for example) the surgeon knows intuitively from the "feel" of the scalpel 10 that the guard 11 is "on", covering the blade 12, and that the edge on the blade 12 is either "up" or "down". The surgeon may retract the guard 11, easily and conveniently, using only one hand and without taking his (or her) eyes away from the patient or the instrumentation in the operating room. The detent means is within the "meaty" portion of the handle 24, that is, within the (vertical) longitudinal center plane 30 thereof, thereby taking maximum advantage of the handle material and, conversely, facilitating a strong detent action. This strong detent action between the guard 11 and the handle 24 provides not only a tactile indication, but also an auditory "click" that the guard 11 has been moved into its alternate desired position, that is, retracted to expose the blade 12 or advanced to cover the blade 12. The detented action is "solid" and prevents inadvertent or accidental movement of

the guard 11 during a surgical procedure or in transferring the scalpel 10. A stop means between the guard 11 and the handle 24, including the closed slot 25 and the transverse pin 26, is independent of the detent means itself; this improves the reliability of the instrument. The guard 11 closely straddles the handle 24 and maintains the desired "slim line" appearance; and the added weight of the guard 11 is relatively insignificant and does not detract from the overall balance, feel and handling of the lightweight scalpel 10. The components of the overall assembly of the scalpel 10 may be manufactured conveniently and economically out of readily available materials, and the scalpel may be sterilized in an autoclave for repeated usage.

With reference to Figs. 15-17, the blade 12 has a closed slot 50 which fits over a laterally-extending longitudinal rib 51 formed on the forward end 52 of the handle 24, thereby removably mounting the blade 12 to the scalpel 10.

In a preferred embodiment, as shown more clearly in Figs. 15 and 16, the forward end 52 of the scalpel body 10 has a shoulder 53 substantially at right angles thereto. This shoulder 53 corresponds to an angled shoulder 54 on a conventional non-guarded scalpel S as shown in Fig. 17. The angled shoulder 54 cooperates with a conventional blade (not shown) having a rearward angled portion complementary to the angled shoulder 54.

The improved blade 12 of the present invention has a rearward shoulder or edge 55 which is substantially at right angles thereto (as shown more clearly in Fig. 16) and complementary to the right angle shoulder 53 on the scalpel 10. Thus the improved blade 12 fits snugly against the shoulder 53 when the blade 12 is removably mounted on the scalpel 10.

The conventional scalpel blades (not shown) cannot be fitted to the improved scalpel 10 of the present invention. However, and as shown more clearly in Fig. 17, the improved blade 12 of the present invention can be fitted to a conventional non-guarded scalpel S, if desired, as well as to the improved scalpel 10 of the present invention.

With reference to Figs. 18-20, the detent member 29' has an externally-tapered self-aligning portion 32', thereby piloting the detent member 29' into its respective detent pocket 42 and assuring a "solid" detent action between the guard 11 and the handle 24, and thereby compensating for any misalignments or tolerance accumulations in the manufacture and assembly of the guarded surgical scalpel 10.

With reference to Figs. 21-25, the improved guarded surgical scalpel 100 includes a generally-tubular housing providing a handle 101 having a rectangular cross-section, as shown more clearly in Fig. 25. The handle 101 has a closed rearward end 102 and an open forward end 103 and, in this embodiment, is formed from two complementary members

including an upper member 101A and a lower member 101B, respectively. These members 101A and 101B are joined together adhesively or by ultrasonic welding or by other suitable means. The lower member 101B has a central upstanding longitudinally-extending section constituting a cleat 104. This cleat 104 includes a forwardly-extending rib 105 upon which the conventional scalpel blade 106 is mounted.

A guard 107 is telescopically mounted within the handle 101 for sliding or reciprocating movement therein between an advanced position in which the blade 106 is substantially covered or protected against inadvertent or accidental cuts or nicks (Fig. 21) and an alternate retracted position in which the blade 105 is exposed (Fig. 220 for use during a surgical procedure.

More specifically, the guard 107 comprises a substantially inverted U-shaped channel member having a top wall 108 and respective substantially-parallel legs or side walls 109 and 110, respectively, depending therefrom. In this manner, as shown more clearly in Figs. 24 and 25, the channel-shaped guard 107 is slidably mounted between the upper member 101A of the handle 101 and the cleat 104 of the lower member 101B.

The guard 107 is manually retracted and advanced, alternately, by means of a slide button 111 secured to the top wall 108 by a screw 112.

The guard 107 has a two-position resiliently-biased detent means 1132 with respect to the handle 101. This detent means 113 includes a detent ball 114 backed up by a spring 115 lodged in a blind bore 116 in the slide button 111 (Fig. 25). This detent ball 114 is carried by the slide button 111, rides in a closed slot 117 formed in the upper member 101A of the handle 101, and is received (alternately) in respective detent pockets 118 and 119 at the ends of the slot 117. The detent means 113 thereby defines the extent of the longitudinal sliding movement of the guard 107 within the handle 101 and, preferably, provides a relatively-loud audible "click" signaling to the user of the instrument that the guard 107 has been moved into its alternate position (either advanced or retracted). This detent action is positive, avoids accidental or inadvertent movement of the guard 107, yet it is convenient and easy to manually manipulate the telescopic sliding guard 107.

However, the mechanical forces and loading on the guard 107 are taken up by a bearing guide means constituting a stop means 120 (Fig. 25) which is independent of the detent means 113. More specifically, the stop means 120 includes at least one pin 121 carried by the upper member 101A of the handle 101, transversely thereof, and received in respective closed longitudinal slots 122 and 123 formed in the downwardly-depending side walls 109 and 110, respectively, of the inverted channel-shaped guard 107. Preferably, the pin 121 is also received in the

central longitudinal section 104 of the lower member 101B of the handle 101, as shown more clearly in Fig. 25.

The guarded scalpel 100 may be made of plastic (as shown) or metal, if desired, so that the guarded scalpel 100 may be either disposable or reusable. The guard 107 may be formed of a transparent plastic material, as shown in Figs. 21 and 25, so that the blade 106 is clearly visible at all times.

Obviously, many modifications may be made without departing from the basic spirit of the present invention. Accordingly, it will be appreciated by those skilled in the art that within the scope of the appended claims, the invention may be practiced other than has been specifically described herein.

Claims

1. A guarded surgical scalpel (100) having a handle (101) with a blade (106) mounted thereon, characterized by the handle (101) being substantially hollow and having a sliding guard (107) telescopically mounted therein, two-position detent means (113) between the guard (107) and the handle (101), thereby defining an advanced position of the guard (107) in which the blade (106) is substantially covered and an alternate retracted position of the guard (107) in which the blade (106) is exposed, and bearing guide means (120) for the guard, the bearing guide means (120) including a pin (121) carried transversely of the handle (101), and the guard including at least one side wall (109, 110) having a longitudinal slot (122, 123) formed therein and receiving the pin (121).
2. The guarded surgical scalpel (100) of claim 1, further characterized in that the guard (107) is formed as an inverted U-shaped channel (107) having a pair of side walls (108, 109), each of which has a longitudinal slot (122, 123) formed therein for receiving the pin (121).
3. The guarded surgical scalpel of claim 2, further characterized in that the longitudinal slots (122, 123) are closed at each end thereof, such that the bearing guide means (120) provides a stop means (120) for limiting the alternate advanced and retracted positions of the guard (107) with respect to the handle (101), the stop means (120) being independent of the detent means (113).
4. The guarded surgical scalpel (100) of claim 1, further characterized in that the detent means (113) comprises a detent member (114) carried by one of the handle (101) and guard (107), and the other of the handle (101) and guard (107) having a

longitudinal slot (117) receiving the detent member (114).

5. The guarded surgical scalpel (100) of claim 4, further characterized by the longitudinal slot (117) having a pair of spaced-apart detent pockets (118, 119) for alternately receiving the detent member (114).
6. The guarded surgical scalpel (100) of claim 5, further characterized by a detent button (111) disposed above the handle (101), the detent button (111) releasing the detent member (114) from a respective detent pocket (118, 119).
7. The guarded surgical scalpel (100) of claim 6, further characterized in that the longitudinal slot (117) receiving the detent member (114) is formed in the top (101A) of the handle (101).
8. The guarded surgical scalpel (100) of claim 1, further characterized in that the handle (101) includes a lower member (101B) having a longitudinally-extending section constituting a cleat (104), and wherein the cleat (104) is provided with a rib (105) for mounting the blade (106) thereon.
9. A guarded surgical scalpel (100) having a handle (101) with a blade (106) mounted thereon, characterized by the handle (101) being substantially hollow, an inverted U-shaped guard (107) telescopically mounted within the handle (101) for sliding movement therein, two-position resiliently-biased detent means (113) between the guard (107) and the handle (101), thereby defining an advanced position of the guard (107) in which the blade (106) is substantially covered and an alternate retracted position of the guard (107) in which the blade (106) is exposed, and bearing guide means (120) between the guard (107) and the handle (101), the bearing guide means (120) being independent of the detent means (113) and providing a stop means (120) limiting the sliding movement of the guard (107).
10. The guarded surgical scalpel of claim 9, wherein the stop means (120) comprises a pin (121) carried by the handle (101) transversely thereof, and wherein the guard (107) has a pair of parallel side walls (109, 110), each of which has a closed longitudinal slot (122, 123) formed therein and receiving the pin (121).
